

Constructed Stormwater Wetlands

Description

Stormwater wetlands are constructed wetland systems designed to maximize the removal of pollutants from stormwater runoff via several mechanisms: microbial breakdown of pollutants, plant uptake, retention, settling and adsorption. Stormwater wetlands temporarily store runoff in shallow pools that support conditions suitable for the growth of wetland plants. Stormwater wetlands also promote the growth of microbial populations which can extract soluble carbon and nutrients and potentially reduce BOD and fecal coliform levels concentrations.

Like detention basins and wet ponds, stormwater wetlands may be used in connection with other BMP components, such as stormwater forebays and micropools. These engineered wetlands differ from wetlands constructed for compensatory storage purposes and wetlands created for restoration. Typically, stormwater wetlands will not have the full range of ecological functions of natural wetlands; stormwater wetlands are designed specifically for flood control and water quality purposes. Similar to wet ponds, stormwater wetlands require a relatively large contributing drainage area and/or a weather base flow. Minimum contributing drainage areas should be no less than ten acres, although pocket type wetlands may be appropriate for smaller sites if sufficient ground water flow is available.

The use of stormwater wetlands is limited by a number of site constraints, including soils types, depth to groundwater, contributing drainage area, and available land area. Soils, depth to bedrock, and depth to water table must be investigated before designing and siting stormwater wetlands. Medium-fine texture soils (such as sands and silt loams) are best to establish vegetation, retain surface water, permit groundwater discharge, and capture pollutants. At sites where infiltration is too rapid to sustain permanent soil saturation, an impervious

Constructed Stormwater Wetlands

meable liner may be required. Where the potential for groundwater contamination is high, such as runoff from sites with a high potential pollutant load, the use of liners should be required.

Advantages

- Improvements in downstream water quality.
- Settlement of particulate pollutants.
- Reduction of oxygen-demanding substances and bacteria from urban runoff.
- Biological uptake of pollutants by wetland plants.
- Flood attenuation.
- Reduction of peak discharges.
- Enhancement of vegetation diversity and wildlife habitat in urban areas.
- Aesthetic enhancement and valuable addition to community green space.
- Relatively low maintenance costs.

Limitations

- Reduction of nutrients in the fall.
- May be difficult to maintain vegetation under a variety of flow conditions.
- Geese may become undesirable year-round residents if natural buffers are not included in the wetland design.
- May act as a heat sink, and can discharge warmer water to downstream water bodies.
- Depending upon design, larger and more requirements than for other BMPs.
- Until vegetation is well established, pollutant removal efficiencies may be lower than anticipated.
- Relatively high construction costs in comparison to other BMPs.

Requirements

Design

A site appropriate for a stormwater wetland must have adequate water flow and appropriate underlying soils. Baseflow from the drainage area or groundwater must be sufficient to maintain a shallow pool in the wetland and support the vegetation, including species susceptible to damage during dry periods. Underlying soils that are NRCS Types B, C or D will have only small infiltration losses. Sites with type A (sandy) soils have high infiltration rates and may require a geotextile liner or a 15 centimeter (6 inch) layer of clay. After excavation and grading of a basin, at least 10 centimeters (4 inches) of soil should be applied to the site. This material, which may be the previously-excavated soil or other suitable material, is used to provide a substrate in which vegetation can become established.

Constructed Wetlands

Stormwater Wetlands

Wetland Treatment

The design criteria for stormwater wetlands are the same as those for active settling ponds. They can be designed to meet particle size removal efficiencies and treatment volume criteria. However, care must be taken to design the wetland so that the bounce in the pool is compatible with the wetland vegetation. The bounce must be considered in addition to any discharge requirements for particle size, flood control or downstream erosion control settling ponds with special attention to keeping solids from overtaking the vegetation.

Factors which increase the settling rate of suspended solids in stormwater wetlands include:

- Laminar settling in zero-velocity zones created by plant stems
- Anchoring of sediments by root structure, helping to prevent scour in shallow areas
- Increased biological activity removing dissolved nutrients
- Increased biological floc formation

Basic Stormwater Wetland Design Types

Design Criteria and other considerations for the following four wetland types are summarized in Table 2.0

Design Flow Marsh System (Fig. 1)

- Shallow marsh systems are configured with different low marsh and high marsh areas, which are referred to as cells (see Fig. 5). They also include a forebay for coarse particulate settlement before the wetland cell and a micropool at the outlet.
- Shallow marshes are designed with sinuous pathways to increase retention time and contact area.
- Most shallow marsh

ATTRIBUTE	DESIGN No. 1 SHALLOW MARSH	DESIGN No. 2 POND/ WETLAND	DESIGN No. 3 ED WETLAND	DESIGN No. 4 POCKET WETLAND
POLLUTANT REMOVAL CAPABILITY	moderate, reliable removal of sediments and nutrients	moderate to high, reliable removal of nutrients and sediment	moderate, less reliable removal of nutrients	moderate, can be subject to resuspension and groundwater displacement
LAND CONSUMPTION	high, shallow marsh storage consumes space	moderate, as vertical pool substitutes for marsh storage	moderate, as vertical ED substitutes for marsh storage	moderate, but can be shoehorned in site
WATER BALANCE	dry weather baseflow normally recommended to maintain water elevations. Groundwater not recommended as the primary source of water supply to wetland			water supply provided by excavation to groundwater
<u>WETLAND AREA</u> <u>WATERSHED AREA</u>	minimum ratio of .02	minimum ratio of .01	minimum ratio of .01	minimum ratio of .01
CONTRIBUTING WATERSHED AREA	DA of 25 acres or greater, with dry weather Q	DA of 25 acres or greater, with dry weather Q	minimum of ten acres required for ED	1 to 10 acres
DEEP WATER CELLS	forebay, channels micropool	pond micropool	forebay micropool	micropool, if possible
OUTLET CONFIGURATION	reversed slope pipe extending from riser, withdrawn approximately one foot below normal pool. Pipe and pond drain equipped with gate valve			broad crested wier with half round trash rack, and pond drain
SEDIMENT CLEANOUT CYCLE (approximate)	cleanout of forebay every 2-5 years	cleanout of pond every ten years	cleanout of forebay every 2 to 5 years.	cleanout of wetland every 5 to 10 years, onsite disposal and stockpile mulch
NATIVE PLANT DIVERSITY	high, if complex microtopography is present	high, with sufficient wetland complexity and area	moderate, fluctuating water levels impose physiological constraints	low to moderate, due to small surface area and poor control of water levels
WILDLIFE HABITAT POTENTIAL	high, with complexity and buffer	high, with buffer, attracts waterfowl	moderate, with buffer	low, due to small area and low diversity

Constructed Stormwater Wetlands

systems consist of pools ranging from 6 to 180 inches. During normal conditions.

- Shallow marshes may require larger contributing drainage areas than other systems, as runoff volumes are stored primarily within the marshes, not in deeper pools where flow may be regulated and controlled over longer periods of time.

Design 2: Pond/Wetland Systems (Fig. 2)

- Multiple cell systems, such as pond/wetland systems, utilize at least one pond component in conjunction with a shallow marsh component.
- The first cell is typically the wet pond which provides for particulate pollutant removal. The wet pond is also used to reduce the velocity of the runoff entering the system.

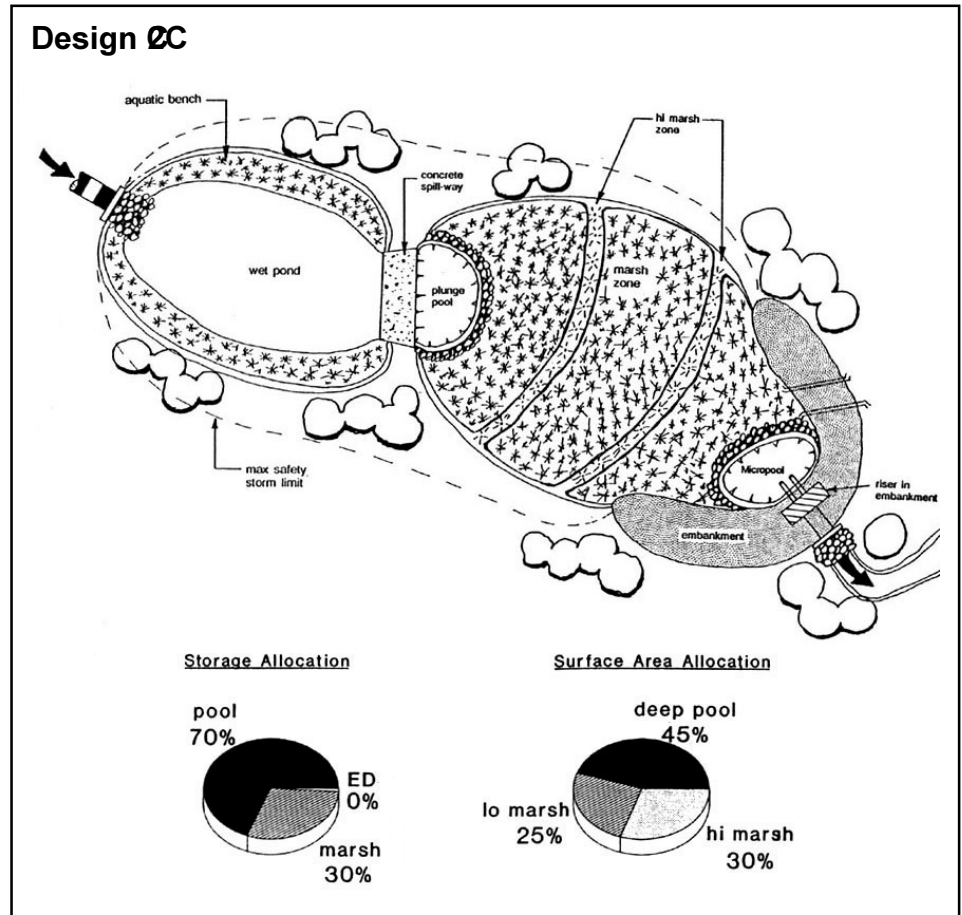

Figure 2. Pond/Wetland System C

Source: Schueler 1992.

- The shallow marsh provides an additional treatment of the runoff, particularly for soluble pollutants. These systems require less space than the shallow marsh systems and generally achieve a higher pollutant removal rate than other stormwater wetland systems.

Design 3: Extended Detention Wetlands (Fig. 3)

- Extended detention wetlands provide a greater degree of downstream channel protection. These systems require less space than the shallow marsh systems, since temporary vertical storage is substituted for shallow marsh storage.
- The additional vertical storage area also provides extra runoff detention above the normal variations.
- Water levels in the extended detention wetlands may increase by as much as three feet after a storm event and return gradually to normal within 24 hours of the rain event.

Constructed Stormwater Wetlands

Requirements Design (continued)

Figure 3. Extended Detention Wetland SystemC

Source: Schueler 1992.9

- The vegetated area in Extended Detention wetlands expands from the normal pool variation to the maximum surface water variation.
- Wetlands plants that tolerate intermittent flooding and dry periods should be selected for the Extended Detention area above the shallow marsh variations.

Design 4: Pocket wetlands (Fig. 4)w

- These systems may be utilized for smaller sites of one to ten acres.
- To maintain adequate water levels, pocket wetlands are generally excavated down to the groundwater table.
- Pocket wetlands which are supported exclusively by stormwater runoff generally will have difficulty maintaining marsh vegetation over extended periods of drought.

Constructed Stormwater Wetlands

General Design Considerations

- Sediment forebays are recommended to increase the velocity and sediment loading to the wetland. They provide the additional benefits of creating sheet flow, extending the flow path, and preventing short circuiting. The forebay should contain at least 10 percent of the wetland's treatment volume and should be 4 to 6 feet deep. The forebay is typically separated from the wetland by gabions, gravel/riprap or by an earthen berm.

- The wetland design should include a buffer to separate the wetland from surrounding areas. Buffers may alleviate some potential wetland nuisances, such as accumulated floatables, odors and or geese.

- A buffer of 25 feet is recommended, plus an additional 250 feet when wildlife habitat is of concern. Leaving trees undisturbed in the buffer zone will minimize the disruption to wildlife and reduce the chance for invasion of nuisance vegetation such as cattails and primrose willow.

- Above ground berms or high marsh wedges should be placed at approximately 50 foot intervals, at right angles to the direction of the flow to increase the dry weather flow path within the stormwater wetland.

- Before the outlet, a four- to six-foot deep micropool (having a capacity of at least ten percent of the total treatment volume), should be included in the design to prevent the outlet from clogging. A reverse slope pipe or a hooded, broad crested weir is the recommended outlet control (See Figure 3b Wet Ponds BMP).

- The outlet from the micropool should be located at least one foot below the normal pool surface. To prevent clogging, trash racks or hoods should be installed on the riser (See Figure 3b Wet Ponds BMP).

- To facilitate access for maintenance, the user should be installed within the embankment (See Figure 3b in Wet Ponds BMP).

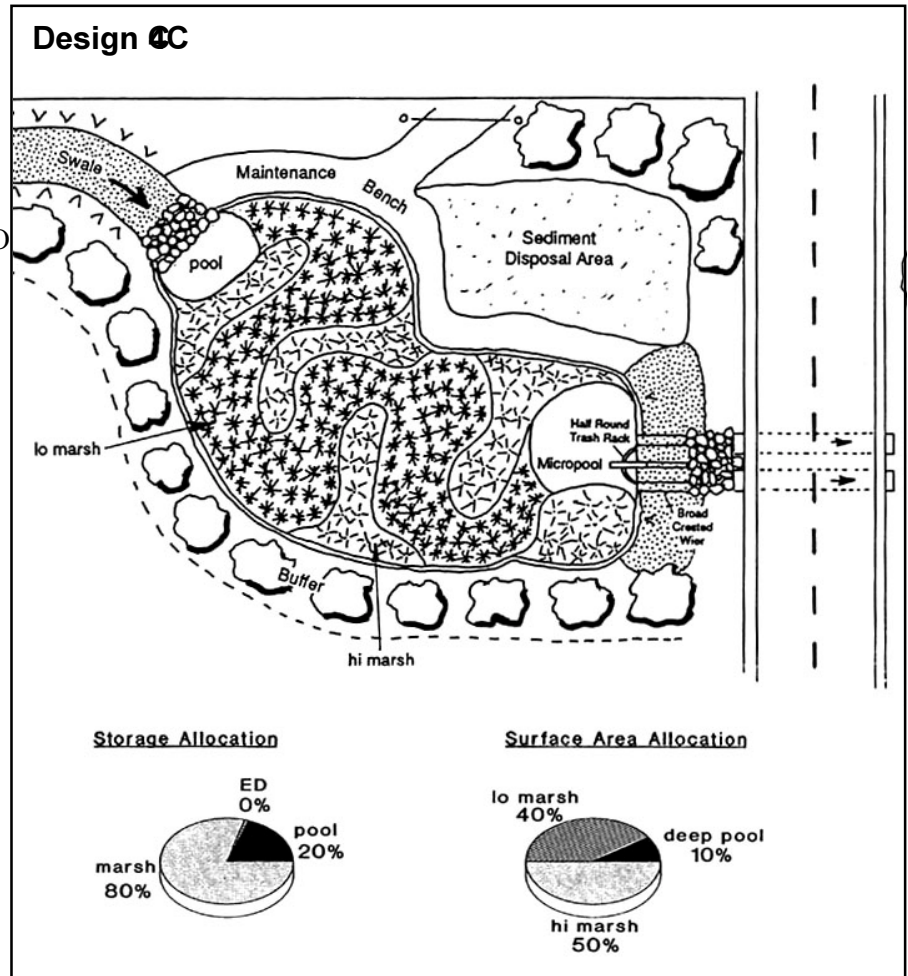

Figure 4. Pocket Wetland SystemC

Source: Schueler 1992.9

Constructed Stormwater Wetlands

Requirements Design (continued)

- Install bottom rainpipe with an inverted bow to prevent sediment clogging in order to completely drain the stormwater wetland for emergency purposes or routine maintenance (See Figure 5b Wet Ponds BMP).
- Fit both the outlet pipe and the bottom rainpipe with adjustable valves at the outlet ends to regulate flows (See Figure 5b Wet Ponds BMP).
- Surround all deep-water cells with a safety bench having a minimum width of 10 feet and a depth of zero to 18 inches below pool's normal water level.
- Remember that wetland treatment systems' effectiveness in removing urban pollutants depends on the system's physical characteristics, such as wetland-size-to-watershed-size ratio, runoff residence time in the wetland and water budget.
- In general, as the wetland-to-watershed area ratio increases, the average runoff residence time increases and the effectiveness of the wetland for pollutant removal also increases.
- Prepare a water budget to monitor that the water supply to the stormwater wetland is greater than the expected loss rate.

Figure 5: Comparative Profiles of the Four Stormwater Wetland Designs

Source: Schueler 1992.

Wetland Size

The stormwater wetlands should be designed to store the water quality treatment volume as required by the local permitting agency. The Metropolitan Council of Governments (Schueler, 1992) has developed guidelines for constructing wetland stormwater basins (see Table 5). Those guidelines recommend a wetland surface area of 10 to 2 percent of the watershed area, depending on the nature of the watershed and the design of the facility.

Constructed Wetlands

Constructed Wetlands

Stormwater Wetlands

Requirements

Design (continued)

During dry weather, flow must be adequate to provide a baseflow to maintain the vegetation. The flow path should be maximized to increase the runoff's contact time with plants and sediments.

Outlet Design

- Extended detention criteria are strongly recommended for the outlet structure design (see Extended Detention).
- An orifice or other outlet structure can be used to restrict the discharge to the required flow. Because of the abundance of vegetation in the wetland, a trash guard should be used to protect the orifice.
- A trash guard large enough so that velocities through it are less than 2 fps will reduce clogging problems.
- Flow from the wetland should be conveyed through an outlet structure that is located within the deeper areas of the wetland. Discharging from the deeper areas using a reverse slope pipe prevents the outlet from becoming clogged. A micropool just prior to the outlet will also prevent outlet clogging.
- The micropool should contain approximately 10 percent of the treatment volume and be 4 to 6 feet deep.
- A adjustable gate-controlled drain capable of dewatering the wetland within 24 hours should be located within the micropool.
- A typical drain may be constructed with an upward-facing inverted siphon. The dewatering feature eases planting and follow-up maintenance.

Wetland Vegetation

(See Figure 6 for techniques to enhance wildlife habitat in stormwater wetlands.)

- Vegetation can be established by three methods: allowing volunteer vegetation to become established (not recommended), planting nursery vegetation, and seeding.
- A higher diversity wetland can be established when nursery plants are used. Vegetation from a nursery should be planted during the growing season—not during late summer or fall—to allow vegetation time to store food reserves for their dormant period.
- Select species adaptable to the broadest ranges of depth, frequency and duration of inundation (hydroperiod). Match site conditions to the environmental requirements of plant selections. Take into account hydroperiod and light conditions.
- Give priority to species that have already been used successfully in constructed wetlands and that are commercially available.
- Allowing species transmitted by wind and water fowl to voluntarily become established in the wetland is unpredictable.
- Wetlands established with volunteers are usually characterized by low plant diversity with monotypic stands of exotic or invasive species.

Constructed Wetlands

Stormwater Wetlands

Sizing Criteria	DESIGN No.1 SHALLOW MARSH	DESIGN No.2 POND/ WETLAND	DESIGN No.3 ED WETLAND	DESIGN No.4 POCKET WETLAND
Runoff Treatment Volume (V_t)	Capture 90% of the Annual runoff volume from site $V_t = (1.25 \text{ inches}) (\text{Runoff Coefficient}) (\text{Site Area})$ Minimum V_t of 0.25 watershed-inches			
Wetland to Watershed Area Ratio	.02	.01	.01	.01
Allocation of Surface Area (%)	20 - deep 40 - lo m. 40 - hi m.	45 - deep 25 - lo m. 30 - hi m.	20 - deep 35 - lo m. 45 - hi m.	10 - deep 40 - lo m. 50 - hi m.
Allocation of Treatment Volume (%)	40 - pool 60 - marsh 0 - ED	70 - pool 30 - marsh 0 - ED	20 - pool 30 - marsh 50 - ED	20 - pool 80 - marsh 0 - ED
Flow Path a. length to width ratio b. dry weather path	1:1 2:1	1:1 2:1	1:1 2:1	NA 2:1
Water Balance	Confirm inflow rate > 0.002 cfs/acre, compute water balance during dry weather			Confirm dry weather water table elevation in field
Extended Detention	Not Employed	Not Employed	EDv = 50% of V_t 12 to 24 hrs ED range ≤ 3 ft.	Not Employed

Table 3: Wetland Sizing Criteria

Source: Schueler 1992.9

Constructed Stormwater Wetlands

Figure 6. Techniques for Enhancing Wildlife in Stormwater Wetlands.

Source: Schueler 1992.9

Requirements Sequencing

- Sites must be carefully evaluated when planning stormwater wetlands. Soils, depth to bedrock, and depth to water table must be investigated before designing and siting stormwater wetlands. A “pondscaping plan” should be developed for each stormwater wetland.
- This plan should include hydrological calculations (or water budget), a wetland design configuration, elevations and grades, a site/soil analysis, and estimated depth zones.
- The plan should also contain the location, quantity, and propagation methods for the stormwater wetland plants. Site preparation requirements, maintenance requirements and maintenance schedule are also necessary components of the plan.
- The water budget should demonstrate that there will be a continuous supply of water to sustain the stormwater wetland. The water budget should be developed during site selection and checked after preliminary site design.

Constructed Stormwater Wetlands

- Drying periods of longer than two months have been shown to adversely affect plant community richness, so the water balance should confirm that drying will not exceed two months.
- After excavation and grading, the wetland should be kept flooded until planting.
- Six to nine months after being flooded and two weeks before planting, the wetland is typically drained and surveyed to ensure that depth zones are appropriate for plant growth. Revision may be necessary to account for any changes in depth.
- Next, the site is staked to ensure that the planting crew spaces the plants within the correct planting zone.

Maintenance

Stormwater wetlands require routine maintenance. The small forebay should be dredged every other year to protect the wetland from excessive sediment buildup. Careful observation of the system over time is required. In the first three years after construction, twice-yearly inspections are required during both the growing and non-growing season. Data gathered during these inspections should be recorded, mapped and assessed.

- The following observations should be made during the inspections:
 - Types and distribution of dominant wetland plants in the marsh.
 - The presence and distribution of planted wetland species.
 - The presence and distribution of invasive wetland species.
 - Signs that invasive species are replacing the planted wetland species.
 - Percentage of unvegetated standing water (excluding the deep water cells which are not suitable for emergent plant growth).
 - The maximum variation of the vegetative condition in this zone, if the sign of variation of the normal pool is being maintained for wetlands with extended zones.
 - Stability of the original depth zones and the microtopographic features, accumulation of sediment in the forebay and micropool, and survival rate of plants in the wetland buffer.
- Inspections should be conducted at least twice a year for the first three years and annually thereafter.
- Regulating the sediment input to the wetland is the priority maintenance activity.
- The majority of sediments should be trapped and removed before they reach the wetlands either in the forebay or in a pond component. Gradual sediment accumulation in the wetland results in reduced water depths and changes in the growing conditions for the emergent plants. Furthermore, sediment removal within the wetland can destroy the wetland plant community. Shallow marsh and extended detention wetland designs include forebays to trap sediment before reaching the wetland. These forebays should be cleaned out every other year.
- Pond/wetland system designs do not include forebays as the wet pond itself acts as an oversized forebay. Sediment cleanout of pond/wetland systems is needed every 10 years.

Constructed Stormwater Wetlands

Requirements Maintenance (continued)

- The key to using the wetland effectively is that the ponds must function so as not to destroy the wetland vegetation. Slight modification of operations and plantings may be necessary as operations proceed.
- Harvesting of wetland vegetation can also be considered to remove nutrients from the wetland system and to minimize nutrient release when vegetation dies in the autumn. This is not generally recommended, but in special cases it will remove the nutrients contained in the vegetation from the system. If vegetation is to be harvested, design features should be included that will allow the wetland to be watered (Schueler, October 1992).
- Maintenance requirements for constructed wetlands are particularly high while vegetation is being established (usually the first three years). This is likely to include removal of invasive species and replanting natives.
- Additionally, routine maintenance tasks, which can be conducted on the same schedule, include removing accumulated trash from trash racks, outlet structures and valves.
